

Iterate on the current design. Do not redesign the product from scratch.

Keep the existing visual language, warmth, typography, spacing, components, and overall “home app” feeling.

I want to improve the information architecture and navigation.

The main change is:

The Home dashboard should be YEAR-focused, while individual months should be drill-down views.

The product should have a very simple mental model:

- Home = How is my year going?
 - Month = What happened this month?
 - Movements = Where did my money go / come from?
 - Plan = What do I want to spend and save?
 - Add movements = I have new financial data to import.
-

1. Simplify the main navigation

Change the primary navigation to only:

- Home
- Movements
- Plan
- Settings

Do NOT include:

- Add transactions
- Import
- Review
- Rules

as primary navigation items.

Importing is an action, not a destination.

Review is just a temporary step during an import.

Rules are an advanced feature and should live inside Settings.

Add a clear global action:

+ Add movements

This should be accessible from anywhere in the app without competing visually with the main navigation.

2. Make Home year-focused

The main Home screen should represent an entire year.

At the top:

2026

with simple previous / next year navigation:

‹ 2026 ›

The first question the page should answer is:

How is my year going?

Show the main annual numbers:

Income
\$XX,XXX

Spent
\$XX,XXX

Saved
\$XX,XXX

Savings rate
XX%

These values represent the selected year to date.

Keep them friendly and readable rather than presenting them like corporate KPIs.

3. Make the months the heart of Home

The most important interaction on the yearly Home should be moving between the year and its individual months.

Create a strong visual section showing the months of the year.

For example:

January
Saved \$3,120
38%

February
Saved \$3,480
41%

March
Saved \$2,940
35%

...

August
Saved \$2,990
34%

Each month should be clickable.

Months without imported data should still appear, but in a quiet empty state.

For example:

September

No movements yet

- Add

Do not make this feel like twelve dashboard cards.

Explore a compact, warm, calendar-like or timeline-like presentation.

The months should make the year feel tangible.

4. Annual trend

Include one clear yearly visualization showing the evolution across months.

Show:

Income
Spending
Savings

from January to December.

The goal is to quickly understand:

- which months were expensive
- which months had higher savings
- how spending is evolving

Keep the chart simple and friendly.

Do not turn Home into an analytics dashboard.

5. Annual insights

Below the month overview, show a few useful year-level insights.

Examples:

Average monthly spending

Average usual cost of living

Total extraordinary spending

Average savings rate

Total saved this year

Most expensive category

Avoid showing too many metrics.

Choose only information that helps understand the year.

6. Spending across the year

Include a section:

Where your money went

Show annual spending by category.

Examples:

Home
Food
Transport
Health & sport
Services
Subscriptions
Shopping & fun
Travel
Gifts & donations
Taxes
Other

Allow clicking a category to explore its movements or trend.

Keep this visually friendly and easy to scan.

7. Month detail

Clicking a month from Home should open a dedicated month view.

Example:

‹ August 2026 ›

The month view answers:

How did August go?

Show:

Income
\$8,756

Spent
\$5,766

Saved
\$2,990

34% saved

Then clearly distinguish:

Your usual expenses
\$4,240

Extra this month
\$1,526
Mostly travel

This distinction is very important.

The user should understand that total spending may be high because of extraordinary expenses while normal lifestyle costs remain lower.

8. Month navigation

Month detail must make moving through time effortless.

Use:

◀ August 2026 ▶

Previous arrow:
July

Next arrow:
September

Clicking “August 2026” should open a fast month/year picker.

Do not require returning to Home to change months.

The user should be able to move:

June → July → August → September

very quickly.

9. Month detail content

Below the monthly summary show:

Where your money went

Budget / plan comparison

Usual vs extraordinary expenses

Savings goal progress

Recent movements

The month view can be more detailed than Home because the user intentionally drilled into that month.

10. Add movements

The global:

+ Add movements

button should open a lightweight flow.

The FIRST thing shown should be the destination month.

Example:

Add movements

Adding to:

[August 2026 ▼]

Drop your bank and card files here.

This is important:

The user must be able to upload data for ANY month at ANY time.

Do not assume they are uploading for the current month.

If the user triggers Add movements while looking at August, preselect August.

If they trigger it from the yearly Home, default to the current month but make the month selector very obvious.

11. Import flow

After uploading files:

August 2026

Santander pesos ✓

Santander dollars ✓

Credit card ✓

204 movements found

187 organized automatically

12 need your help

5 already existed

Primary CTA:

Review 12

If nothing needs review:

Finish August

12. Review is part of Add movements

Do not make Review a separate product section.

It is simply step 2 of adding movements.

The flow is:

Choose month

→ Upload

→ Process

→ Review uncertain movements

→ Finish

Example:

A few things need your help

8 of 12 reviewed

GABRIEL BURSZTEIN

-\$717

Where should this go?

[Gifts & donations ▼]

☒ Remember this for next time

At completion:

August is up to date ✓

Then return to the August month view.

13. Movements

Movements is the searchable history of everything.

It should NOT compete conceptually with “Add movements”.

Movements = browse / search / edit existing data.

Add movements = bring new data into the app.

The Movements screen should have:

Search movements...

Month selector

Category filter

Account filter

Type filter

Default to a useful recent period.

Allow switching between months easily.

Example:

August 2026 ▼

Then group movements naturally by date.

14. Plan

Keep Plan focused on intentions.

It answers:

What do I want my month to look like?

Show:

Expected income

Spending plan

Savings goal

Category budgets

The Plan should define defaults that can apply every month.

Allow individual months to override those defaults when necessary.

Do not make this feel like spreadsheet budgeting software.

15. Settings

Move technical / configuration concepts here:

Accounts

Categories

Income sources

Currency

Savings goal

Rules

Rules should not be something the user needs to understand during normal use.

Most rules should be created naturally through:

Remember this for next time

during Review.

16. Empty months

Design the experience for months without data.

If I open October and nothing has been imported:

October 2026

Nothing here yet.

Add your bank and card movements to see how October went.

[+ Add October movements]

This should feel intentional, not like a broken or empty dashboard.

17. Important interaction principle

Time should feel continuous throughout the app.

The user should never feel trapped in one month.

It should always be obvious:

- what year I am viewing
- what month I am viewing
- how to go to the previous/next month
- how to jump to another month
- which month new movements will be added to

Do not hide the selected time period inside filters.

Make time part of the primary interface.

18. Keep the existing personality

Do NOT turn this iteration into a fintech dashboard.

Preserve the current warm, simple, household-oriented feeling.

It should feel like an app I casually use at home once or twice a month.

Avoid:

- corporate financial dashboards
- banking aesthetics
- dense analytics
- excessive KPI cards
- technical accounting terminology
- complex navigation
- enterprise tables

The experience should feel:

personal
calm
simple
warm
useful

Key hierarchy

The final product hierarchy should be:

HOME / YEAR

“How is 2026 going?”

MONTH

“How did August go?”

MOVEMENTS

“What happened?”

And separately:

+ ADD MOVEMENTS

“Bring new data in.”

This hierarchy should be immediately understandable from the design.

Iterate the existing screens around this model instead of starting over visually.
